```

We present new data probing short-range correlations (SRCs) in nuclei through the measurement of electron scattering off high-momentum nucleons in light nuclei. The inclusive cross section ratios of  ${}^{4}\text{He}/{}^{3}\text{He}$  and  ${}^{12}\text{C}/{}^{3}\text{He}$  are observed to be both x and  $Q^{2}$  independent for 1.5 < x < 2, confirming the previously observed dominance of two-nucleon short-range correlations. The cross section ratios for x > 2 do not agree with an earlier measurement which suggested that three-nucleon correlations dominated the interaction in this  $Q^2$  range. While 3N-SRCs may have an important contribution, these data suggest that they cannot be isolated in the same simple fashion as 2N-SRCs.

PACS numbers: 13.60.Hb, 25.10.+s, 25.30.Fj

77 Fermi momentum [2–4].

61

62

63

In the dense and energetic environment of the nucleus, 79 nucleons have a significant probability of interacting at 80 distances  $\leq 1$  fm, even in light nuclei [? ? ]. Pro-81 tons and neutrons interacting through the strong, short-82 distance part of the NN interaction give rise to pairs of 83 nucleons with large momenta. These high-momentum 84 pairs, referred to as short-range correlations (SRCs), 85 are the primary source of high-momenta in nuclei [5-86 7, well above the typical scale of the Fermi momentum  $_{87}$   $(k_F \approx 300 \text{ MeV/c})$  associated with the shell model pic-88 ture of nuclear structure. For momenta below  $k_F$ , we  $_{89}$  observe shell-model behavior which is strongly A depen-90 dent, while two-body physics dominates above  $k_F$  result-91 ing in a universal structure for all nuclei that is steered 92 by the details of the NN interaction [8?, 9].

94 ble through kinematics, as follows, to isolate events in 140 behavior arising from 3N-SRCs by examining scatter-101 Elastic scattering from a stationary proton corresponds 147 tios of heavier nuclei to <sup>3</sup>He allows a similar examina-105 tering at x > 1 is beyond the kinematic threshold for 151 three nucleons have large relative momenta but little to-106 scattering from a free nucleon. At values of x slightly 152 tal momentum. 3N-SRCs could come from either three-107 greater than unity, scattering can occur either from nu- 153 nucleon forces or multiple hard two-nucleon interactions.

Understanding the complex structure of the nucleus 114 Because the momentum distribution of the nucleus is 69 remains one of the major uncompleted tasks in nu- 115 not a physical observable, one cannot directly extract and 70 clear physics, and significant questions remain about 116 study its high-momentum component. One can, how-71 the high-momentum components of the nuclear wave- 117 ever, test the idea of a universal structure of the high-72 function. This important aspect of nuclear structure is 118 momentum components by comparing scattering from 73 not described by the shell model description. This high- 119 different nuclei at kinematics which require that the 74 momentum strength appears at low momenta in Mean 120 struck nucleon have a large initial momentum |8|. Previ-75 field calculations [1] which subsequently over predict the 121 ous measurements at SLAC and Jefferson Lab revealed 76 cross section for proton knock-out reactions below the 122 a universal form to the high-momentum distributions of 123 the struck nucleons [6, 7, 10? ? ? ? ]. In these exper-124 iments, the cross section ratios for inclusive scattering 125 from heavy nuclei to the deuteron were shown to scale, 126 i.e. be independent of x and  $Q^2$ , for  $x \gtrsim 1.5$  and  $Q^2 \gtrsim$ 127 1.5 GeV<sup>2</sup>, corresponding to scattering from nucleons with 128 momenta above 300 MeV/c. Other measurements have 129 demonstrated that these high-momentum components 130 are dominated by high-momentum n-p pairs [11? ? ? 131 ? ? ], meaning that the high-momentum components 132 in all nuclei have a deuteron-like structure. While final-133 state interactions (FSI) decrease with increasing  $Q^2$  in 134 inclusive scattering, FSI between nucleons in the corre-135 lated pair may not disappear. It is typically assumed that 136 the FSI are identical for the deuteron and the deuteron-137 like pair in heavier nuclei, and thus cancel in these ra-138 tios [7, 8].

In the case of inclusive electron scattering it is possi- 139 This approach can be extended to look for universal 95 which the electron interacts with high-momentum nucle- 141 ing at x > 2 (beyond the kinematic limit for scattering <sub>96</sub> ons. The electron transfers energy,  $\nu$ , and momentum, <sub>142</sub> from a deuteron). Within the simple SRC model [5],  $97\vec{q}$ , to the struck nucleon by exchanging a virtual photon 143 the cross section is composed of scattering from one-98 with four momentum transfer  $q^2 = -Q^2 = \nu^2 - |\vec{q}|^2$ . 144 body, two-body, etc... configurations, with the one-body <sub>99</sub> It is useful in this case to define the kinematic variable <sub>145</sub> (shell-model) contributions dominating at  $x \approx 1$ , while  $_{100} x = Q^2/(2M_p\nu)$ , where  $M_p$  is the mass of the proton.  $_{146}$  2N-SRCs (3N-SRCs) dominate as  $x \to 2(3)$ . Taking ra- $_{102}$  to x=1, while inelastic scattering must occur at x<1.  $_{148}$  tion of the target ratios for x>2, where the simple 103 In a nucleus, the momentum of the nucleon produces 149 SRC model predicts a universal behavior associated with  $_{104}$  a broad quasielastic peak centered near x=1. Scat-  $_{150}$  three-nucleon SRCs (3N-SRCs) - configurations where 108 cleons with the modest momenta expected from the mean 154 The first such measurement [10] observed x-independent <sub>109</sub> field, or from high-momentum nucleons associated with <sub>155</sub> ratios for x > 2.25. This was interpreted as a result of 110 SRCs. As x increases, larger initial momenta are required 156 3N-SRCs dominance in this region. However the ratios 111 until scattering from nucleons below the Fermi momen- 157 were extracted at relatively small  $Q^2$ , and the  $Q^2$  depen-112 turn is kinematically forbidden, isolating scattering from 158 dence was not measured. In the experiment of Ref. [?], <sub>113</sub> high-momentum nucleons associated with SRCs [7? -9]. <sub>159</sub> at higher  $Q^2$ , the  ${}^4\text{He}/{}^3\text{He}$  ratios were significantly larger. 161 tions have been cleanly identified and observed to domi- 217 <sup>4</sup>He targets because of the high-current electron beam. 162 nate at some large momentum scale is as yet unanswered. 218 We made dedicated measurements over a range of beam 164 E08-014 [12], which focused on precise measurements of 220 the current dependence of the target density. The effect  $_{165}$  the x and  $Q^2$  dependence of the A/ $^3$ He cross section ra- $_{221}$  was large and varied with the position along the target, 166 tios at large x. A 3.356 GeV electron beam with currents 222 and the measurements were used to determine the den- $_{167}$  ranging from 40 to 120  $\mu$ A impinged on nuclear targets,  $_{223}$  sity loss and thus the effective target thicknesses of the and scattered electrons were detected in two nearly iden- 224 measurement. Since much of the model dependence will 169 tical High-Resolution Spectrometers (HRSs) [13]. Data 225 be target independent, a conservative 5% normalization 170 were taken on six targets: three 20-cm cryogenic targets 226 uncertainty was applied on the ratio of cryotargets to 171 (liquid <sup>2</sup>H and gaseous <sup>3</sup>He and <sup>4</sup>He) and thin foils of 227 account for target density uncertainties. <sup>12</sup>C, <sup>40</sup>Ca and <sup>48</sup>Ca. We focus here on the results from <sup>228</sup> The measured events, corrected for inefficiencies and  $_{173}$  the light nuclei,  $A \leq 12$ , which were taken to examine  $_{229}$  normalized to the integrated luminosity, were binned in 174 the 3N-SRC region, while the Calcium data were taken 230 x and compared to the simulated yield. The simulation 175 to examine the isospin dependence in the 2N-SRC kine- 231 uses a y-scaling cross section model [15?] with radiative

178 (VDCs) for particle tracking, two scintillator planes for 234 effective momentum approximation [?], and are 2% or 179 triggering and timing measurements, and a gas Čerenkov 235 smaller for all data presented here. The combined sys-180 counter and two layers of lead-glass calorimeters for par- 236 tematic uncertainty, neglecting the normalization uncer-181 ticle identification [13]. Scattering was measured at 237 tainty due to target thickness uncertainty, is XX-YY%,  $_{182}\theta = 21^{\circ}, 23^{\circ}, 25^{\circ}, \text{ and } 28^{\circ}, \text{ covering a } Q^2 \text{ range of } 1.3-238 \text{ and is generally the largest contribution to the uncer _{183}$  2.2 GeV<sup>2</sup>. A detailed description of the experiment and  $_{239}$  tainties in the ratios except at larger x values where the 184 data analysis can be found in Ref. [14].

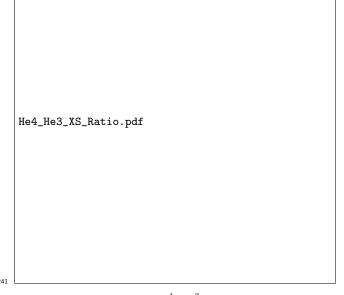

The data analysis is relatively straightforward, as the 186 inclusive scattering at x > 1 yields low rates and a small 187 pion background. The trigger and tracking inefficiencies 188 are small and applied as a correction to the measured 189 yield. Electrons are identified by applying cuts on the sig-190 nals from both the Cerenkov detector and the calorime-191 ters. The cuts yield > 99\% electron efficiency with neg-192 ligible pion contamination. The overall dead-time of the 193 data acquisition system (DAQ) was evaluated on a run-194 by-run bases. To ensure a well-understood acceptance, 195 the solid angle and momentum acceptance were limited 196 to high-acceptance regions and a model of the HRSs [14] 197 was used to apply acceptance corrections.

The scattered electron momentum, in-plane and out-199 of-plane angles, and vertex position at the target can be 200 reconstructed from the VDC tracking information using 201 the optics matrices determined in earlier experiments. 202 For the right HRS, the third quadrupole was unable to 203 run at its full current, and so data were taken in a mod-204 ified tune with at 15% reduction in its field. Optics data 205 were taken to correct for the modified tune. Many of the 206 systematic uncertainties in the spectrometers are corre-207 lated, so we took the conservative approach of applying 208 these uncertainties to the combined result from the HRS-209 L and HRS-R data.

The cryogenic targets have a large background from 211 scattering in the cell walls. We apply a  $\pm 7$  cm cut around 212 the center of the target, removing > 99.9% of the events 213 from target endcap scattering, as determined from mea-214 surements on empty target cells. One of the largest con- 249 are in good agreement with the CLAS [10] and E02-019 [?

160 Consequently, the question of whether 3N-SRC contribu- 216 get density reduction due to heating of the <sup>2</sup>H, <sup>3</sup>He, and The results reported here are from JLab experiment 219 currents and used the variation of the yield to measure

232 corrections applied using the peaking approximation [14? Each HRS consists of a pair of vertical drift chambers 233]. Coulomb corrections are applied within an improved 240 statistical uncertainty becomes larger.

<sup>242</sup> FIG. 1. (Color online) The <sup>4</sup>He/<sup>3</sup>He cross section ratio for  $_{243} Q^2 > 1.4 \text{ GeV}^2$  (23° and 25° scattering), along with results 244 from CLAS [10] and Hall C (E02-019) [?]. The error bars <sup>245</sup> include statistical and systematic uncertainties; the global 5% 246 normalization uncertainty is not shown.

Figure 1 presents the  ${}^4\mathrm{He}/{}^3\mathrm{He}$  cross section ratio for  $_{248}$  our  $Q^2 > 1.4 \text{ GeV}^2$  data. In the 2N-SRC region, our data 215 tributions to the systematic uncertainty comes from tar- 250 results, revealing a plateau for 1.5 < x < 2. At x > 2, <sub>252</sub> but consistent within uncertainties with the E02-019 re- <sub>306</sub> other nuclei for x > 2.5, yielding the rise in the  $^4$ He/ $^3$ He 253 sults. This is consistent with the explanation provided in 307 ratios discussed above. In the naive SRC model, it is 254 a recent comment [?] which concluded that the observed 308 assumed that the high-x cross section comes from the 255 plateau was likely the result of large bin-migration effects 309 contributions of stationary 2N- and 3N-SRCs. The pre-256 resulting from the limited CLAS momentum resolution. 310 diction of scaling in this model breaks down due to the

258 butions beyond 2N-SRCs, we do not observe the 3N-SRC 312 moving SRCs in heavier nuclei. For the most recent ex-259 plateau expected in the naive SRC model. In this model, 313 traction of 2N-SRCs from the A/2H ratios [?], the effect 260 the prediction of scaling as an indication of SRC domi- 314 of the 2N-SRC motion in heavier nuclei was estimated 261 nance is a simple and robust way to test for 2N-SRCs, 315 and found to give a small enhancement of the ratio in 262 but it is less clear how well it can indicate the presence of 316 the plateau region, with little distortion of the shape until  $_{263}$  3N-SRCs. For 2N-SRCs, one can predict a priori where  $_{317}$  x > 1.9 [?] where the ratio rises rapidly to infinity. For  $_{264}$  the plateau should be observed since for a given  $Q^2$  value,  $_{318}$  3N-SRCs, motion of the correlations produces a similar  $_{265}$  x can be chosen to require a minimum nucleon momen-  $_{319}$  rise which begins well before the kinematic limit at  $x \approx 3$ . 266 turn above the Fermi momentum, strongly suppressing 320 This picture is also consistent with the observation that <sub>267</sub> single-particle contributions. It is not clear what values <sub>321</sub> the x > 2.5 increase in the ratio is larger for  ${}^{12}\mathrm{C}/{}^{3}\mathrm{He}$ . 268 of x and  $Q^2$  are required to suppress 2N-SRC contribu- 322 However, a clear interpretation of the large x behavior of 269 tions well enough to isolate 3N-SRCs; much larger  $Q^2$  323  $^{12}$ C/ $^3$ He is more difficult. At very large x values, where 270 values may be required to isolate 3N-SRCs and see anal- 324 the cross section drops rapidly, the data are very sensi-271 ogous plateaus at x > 2.5.

 $_{273}$  FIG. 2. (Color online) The  $^{4}$ He/ $^{3}$ He (top) and  $^{12}$ C/ $^{3}$ He (bot-274 tom) cross section ratios for all angles, along with results from 275 CLAS [10] and Hall C (E02-019) [? ] measurements. The 276 solid lines correspond to a simple cross section model based 277 on parameterized momentum distributions.

<sub>279</sub> the deuteron cross section falls to zero for  $x \to M_D/M_p \approx$  $_{280}$  2, causing the  $A/^2H$  ratio to rise sharply to infinity.  $_{335}$  tional effects due to the difference in resolution between <sub>281</sub> Both the previous high- $Q^2$  deuterium data and our sim- <sub>336</sub> the foil targets and the 20cm 3, 4He targets. 282 ple cross section model, based on a parameterization of 337 We have performed high-statistics measurements of the the nulcon momentum distribution in the nucleus, show 338 <sup>4</sup>He/<sup>3</sup>He and <sup>12</sup>C/<sup>3</sup>He cross section ratios, confirming 284 that the sharp drop of the deuteron cross section does 339 the results of the low-statistics measurements from Hall 285 not occur until  $x \approx 1.9$ , resulting in a clear plateau for 340 C [?] and showing a clear disagreement with the CLAS  $_{286}$  1.5 < x < 1.9. For  $^{3}$ He, our cross section model shows  $_{341}$  data [10]. This supports the idea that the CLAS data 287 a similar falloff of the <sup>3</sup>He cross section starting near <sub>342</sub> were limited at large x by bin-migration effects due to the  $_{288} x \approx 2.5$ , thus yielding a rise in the A/3He ratio that  $_{343}$  spectrometer's modest momentum resolution [?]. We 289 sets in at much lower x values. This rapid rise in the 344 do not observe the plateau predicted by the naive SRC <sup>290</sup> A/<sup>3</sup>He ratio as one approaches the <sup>3</sup>He kinematic thresh- <sup>345</sup> model, but explain why the prediction for the inclusive 291 old shifts to lower x as  $Q^2$  increases, as seen in both the 346 ratios in the 3N-SRC regime are not as robust as those for 292 data and model in Fig 2. So while the plateau is expected 347 2N-SRC. While we do not observe the predicted plateau, 293 to set in at lower x values as  $Q^2$  increases, as seen in the 348 this does not demonstrate that 3N-SRCs are unimportant <sup>294</sup> 2N-SRC region [6, 10], the large-x breakdown also shifts <sup>349</sup> in this region. Even if the cross section is dominated by 295 to lower x values. Thus, it is not clear whether higher  $Q^2$ 296 measurements will yield a clean way to isolate and study 351 plateau due to the motion of the 3N-SRCs. 297 3N-SRCs.

<sup>299</sup> FIG. 3. (Color online) Cross sections of <sup>2</sup>H, <sup>3</sup>He, <sup>4</sup>He and <sup>12</sup>C 300 at 25°. The uncertainties include statistical and systematic  $_{301}$  uncertainties. The normalization uncertainties, ranging from  $_{356}$  limited region in x where the correction for the motion of 302 2-5%, are not shown.

251 our ratios are significantly larger than the CLAS data, 305 Fig. 3. The <sup>3</sup>He cross section falls more rapidly than the While the rise in the ratio above x = 2 indicates contri- 311 difference between stationary SRC in <sup>2</sup>H (or <sup>3</sup>He) and 325 tive to the spectrometer resolution. When comparing two 326 thin targets, or two extended targets, the acceptance and 327 resolution effects cancel, stronly suppressing such effects  $_{328}$  in the target ratios. However, in the ratio of  $^{12}\text{C}/^{3}\text{He}$ , the 329 variation of the resolution with target length and the pos-330 sible impact of correlations between the scattering angles 331 and the reconstructed target position can yield different 332 resolution effects for the two targets. So while the rise For 2N-SRCs, the plateau must eventually disappear as  $^{333}$  in the  $^{12}$ C/ $^3$ He can be explained by the comparison of 334 moving 3N-SRCs to stationary ones, there can be addi-

350 3N-SRCs, the inclusive scattering ratios may not show a

While the  $A/^3$ He ratios do not provide a direct signa-353 ture of 3N-SRCs, it should still be possible to use inclu-354 sive scattering to look for contributions of 3N configura-355 tions in nuclei. The biggest obstacle appears to be the 357 any 3N-SRCs in heavy nuclei is small. This problem can 358 be avoided if one compares the <sup>3</sup>He scattering at large The absolute cross sections for scattering from <sup>3</sup>He, <sup>359</sup> x with a model of the contributions of moving 2N-SRCs <sup>4</sup>He and <sup>12</sup>C at a scattering angle of 25° are shown in <sup>360</sup> in <sup>3</sup>He. The contribution of 3N-SRCs would appear as <sup>361</sup> an increase in the cross section relative to what is ex-<sup>362</sup> pected when modeling scattering from <sup>3</sup>He in terms of <sup>363</sup> single-particle strength and 2N-SRC contributions, in-<sup>364</sup> cluding precise, quantitative corrections for the motion <sup>365</sup> of the 2N-SRCs. However, because this is a comparison <sup>366</sup> to theory, rather than a comparison of SRCs within two <sup>367</sup> nuclei, one can no longer rely on final-state interactions <sup>368</sup> canceling in the comparison, and these effects would have <sup>369</sup> to be modeled.

It will be important for such comparisons to be performed over a range of  $Q^2$ , making the data to be taken
